Prepared for: The Six Treaty Tribes of Oklahoma

ABSTRACT-Releases of hazardous substances, including Cd, Pb, and Zn from the Tri-State Mining District, Ottawa County, Oklahoma have caused concern among Tribal members living downstream of this historic mining area regarding contaminant levels present in traditionally gathered plants. Plants and soils from gathering areas located in floodplain habitats were sampled and analyzed for Cd, Pb, and Zn concentrations to investigate this potential health hazard from consumption of culturally significant plants and to identify an exposure pathway from contaminated soils, causing injury to these culturally significant plants. A significant, positive correlation was shown for metal concentrations in plant tissues and soil (Pb: r = 0.48, p = 0.00; Zn: r = 0.70, p = 0.00). These results indicate a contamination pathway in which culturally significant plants are exposed to heavy metal concentrations via floodplain soils. Plant metals were compared to the provisional tolerable weekly intakes (PTWI) recommended by the Joint FAO/WHO Expert Committee on Food Additives. In one serving for a child (23 kg), 35% of Cd, 42% for Pb, and 2% for Zn in plant tissue samples exceeded metal concentration for the PTWI. In one serving for an adult (70 kg), 21% Cd, 34% for Pb, and 1% for Zn exceeded metal concentration for the PTWI (Table 5). These results indicate that Tribal consumption of only one serving of culturally important species per week from impacted gathering areas pose serious health risks from exposure of Cd, Pb, and Zn to Tribal members, especially to children. Based on these results, culturally significant plants have been injured as defined by DOI regulations that state "...an injury to a biological resource has resulted from a release of a hazardous substance if the concentration of the substance is sufficient to exceed action or tolerance levels established under section 402 of the Food, Drug and Cosmetic Act in edible portions of organisms".. Injured species were found to be widespread across the study area and were collected adjacent to all the water bodies in question in this study; namely, Tar Creek, Elm Creek, Lost Creek, Spring River, and Grand River. Service loss due to [i]njuries to plant species is most likely greater than what is estimated within this study since Tribal members commonly consume multiple servings of multiples species of traditional plants per week. A hypothetical weekly consumption scenario

indicated that an adult Tribal member, 17,054% of their allowable weekly limit intake for Cd, 22,461% for Pb, and 2,320% for Zn. Additionally, a child Tribal member would have consumed 25,952% of their allowable weekly limit for Cd, 34,180% for Pb, and 3,531% for Zn. These calculations highlight the severe magnitude of heavy metal exposure to Tribal members who gather and consume traditional plants within the Grand Lake watershed. The results of this study can be used by Tribes and government entities to make decisions on managing natural resources to protect Tribal traditional lifeways.

Key Words: heavy metals, wild plants, culturally important plants, consumption, Grand Lake watershed, Native American, traditional lifeways.

INTRODUCTION

Tribal communities rely on the use of wild plants in order to maintain their traditional lifeways. Gathering of wild plants takes place year round for crafts, ceremonies, food, and medicine. Important seasonal species are canned, dried, or frozen and stored for use throughout the year. As a result of such reliance and uses, Tribal consumption rates of wild plants are typically higher than the general population. Commonly, all meals during any given day are supplemented by wild plants. Each generation has retained this sacred knowledge through songs, stories, and first-hand teachings from Tribal elders (Garvin et al., 2009).

Gathering of wild plants is often necessary for survival of Tribal communities. Poverty and unemployment rates among Tribal communities are the highest for any ethnic group in the U.S, with nearly one in three individuals living below the poverty line. Because they are highly dependent upon their natural resources, Tribal communities are more susceptible to adverse health effects from pollution. In many cases, they have greater exposure risks than the general population as a result of their dietary practices and unique cultures that embrace the environment (Walker, et al., 2012).

In northeastern Oklahoma, heavy metal runoff from historic lead and zinc mining operations has contaminated natural resources, including floodplain areas used by Tribal communities to gather edible wild plants. Historic mining operations within the Tri-State Mining District (TSMD) encompass approximately 1,188 square miles in southeastern Kansas, southwestern Missouri, and northeastern Oklahoma (Brosius and Sawin, 2001). The Oklahoma portion of the TSMD is referred to as the Tar Creek Superfund Site (TCSS). Two major rivers (Spring River and Neosho River) and their watersheds combine to form Grand River and drain the entire TSMD into Grand Lake o' the Cherokees (Grand Lake). Lands and natural resources located downstream of the TMSD and within jurisdictional areas of ten Tribes have and continue to be exposed to upstream heavy metals sources from TMSD, and potentially render certain resources (i.e. wild plants) unsafe for use or consumption within Tribal communities.

In 2010, the Six Treaty Tribes of Oklahoma¹ analyzed heavy metal concentrations of floodplain soils (clay fraction) within their jurisdictional lands located in the Grand Lake watershed. Heavy metal concentrations in floodplain soils that were located approximately 8 miles downstream of the TSMD were as high as 24.9 mg/kg Cd, 250 mg/kg Pb, and 4,400 mg/kg Zn (Garvin et al., 2010). In comparison, background concentrations within soils have previously been established within the Tri-State area as 0.6 mg/kg Cd, 20 mg/kg Pb, and 100 mg/kg Zn (Pope, 2004). The number of transects that exceeded background concentrations are shown in Appendix A. Results of this study determined that heavy metals have contaminated floodplain soils within Tribal jurisdictions that are located as far south as the upper end of Grand Lake.

¹ These are the Cherokee Nation, Eastern Shawnee Tribe of Oklahoma, Miami Tribe of Oklahoma, Ottawa Tribe of Oklahoma, Seneca-Cayuga Tribe of Oklahoma, and Wyandotte Nation of Oklahoma. These Tribes formed the Six Treaty Tribes of Oklahoma in 2009 to address specific Tribal natural resource concerns.

Recent surveys² administered by the Six Treaty Tribes of Oklahoma in 2009 and 2011 to Tribal members living within northeastern Oklahoma indicated that gathering culturally significant plants was considered to be very important in maintaining traditional lifeways. It was also indicated that the majority of culturally important species used by Tribal members are gathered from floodplain habitats of the Grand Lake watershed (Garvin et al., 2011). Floodplains are very important gathering locations for Tribal communities because they are easily accessed by boat and support a wide variety of culturally significant plant species, both in quantity and diversity. Results from the recent sediment study and Tribal surveys have raised interrelated concerns regarding the impact of ongoing heavy metals contamination on wild plants within floodplain areas and the potential health risks posed to Tribal communities who gather and consume wild plants from these areas.

As defined by the Department of the Interior (DOI), an injury to a biological resource has resulted from a release of a hazardous substance if the concentration of the substance is sufficient to exceed action or tolerance levels established under section 402 of the Food, Drug and Cosmetic Act, 21 U.S.C. § 342, in edible portions of organisms. 43 CFR § 11.62(f)(1)(ii). The regulations further specify that [i]njury to biological resources, as such injury is defined in § 11.62(f)(1)(ii), may be determined by using methods acceptable to or used by the Food and Drug Administration or the appropriate State health agency in determining the levels defined in that paragraph. 43 CFR § ``.64(f)(4) Methods that U.S. Food and Drug Administration (FDA) accepts or uses for these purposes include those used by the Joint Food and Agriculture Organization (FAO)/World Health Organization (WHO) Expert Committee on Food Additives to establish tolerable human intakes of Cd, Pb, and Zn contained in foods. These limits are referred to as the provisional tolerable weekly intake (PTWI) and represent the acceptable human weekly exposure to contaminants within foods (FAO/WHO, 2004).

The methods used by the FAO/WHO to establish tolerable human intakes of Cd, Pb, and Zn contained in foods are methods that the FDA accepts or uses to determine whether concentrations of these metals are sufficient to exceed action or tolerance levels established under section 402 of the Food, Drug and Cosmetic Act, 21 U.S.C. § 342 in edible portions of organisms (B. Harper, personal communication, March 11, 2014). Injury to culturally important plant species can therefore be determined under 43 CFR § 11.62(f)(1)(ii) by assessing heavy metal concentrations in plant species, using these data to calculate the PTWI for each species, and then comparing the PTWI to approximate serving sizes and the frequency of consumption by Tribal members for each species. Any species that contains higher concentrations than the weekly tolerable limit based on Tribal consumption frequency is injured under 43 CFR § 11.62(f)(1)(ii).

The objectives of this study were to 1) assess the concentrations of Cd, Pb, and Zn in culturally significant plants used by the Six Treaty Tribes of Oklahoma, 2) compare heavy metal concentrations in culturally significant plants to concentrations within floodplain soils to identify

² Data from survey can be accessed from the Eastern Shawnee Tribe of Oklahoma Environmental Department. For contact information visit http://www.estoo-nsn.gov/.

metal pathways, 3) calculate PTWI values for culturally significant plants, and 4) identify injured culturally significant plants based on exceedances of the PTWI as provided in 43 CFR § 11.62(f)(1)(ii).

METHODS

Located along the southwestern flank of the Ozark Mountains, the abandoned TSMD encompasses 1,188 square miles in southeastern Kansas, southwestern Missouri, and northeastern Oklahoma. Commercial extraction of lead and zinc bearing ores within the TSMD took place for nearly 120 years (1850-1970), peaking between 1918 and 1941 (Brosius and Sawin, 2001). Mining occurred within a 50-150 ft thick limestone and chert bearing strata known as the Boone Formation or Boone Aquifer. As part of the mining process, the Boone Formation was continuously dewatered to keep the mines from flooding. Mining and milling operations within the TSMD resulted in the accumulation of abandoned mine wastes on the ground surface in the form of fine sediments within flotation/tailing ponds and large piles of gravel-size chert known as chat. Mining activities also created an extensive and interconnected network of underground mine workings. When the mining finally ceased in 1970, the pumps used to dewater the mines were shut off, causing the mines to fill with highly acidic water that contained elevated concentrations of SO₄, Pb, Zn, Cd, and Fe (USEPA 2000). Metals located in the mines and in waste materials on the surface have led to contamination of not only the groundwater, but to surface water, sediments, and floodplain soils within the Grand Lake watershed (Davis and Schumacher 1992; Ankley et al. 1996; USEPA 2000; USGS 2009; Garvin et al., 2010).

The study location for this project is the Oklahoma portion of the Grand Lake Watershed (Figure 1). Figure 1 shows the jurisdictional boundaries for all Tribes in the area. The two major rivers that make up the watershed are the Neosho River and Spring River. Two important tributaries of the Neosho River drain upstream mining areas: Elm Creek drains mining areas in Cherokee County, KS and Tar Creek drains the TCSS in Ottawa County, OK. Spring River drains several portions of the Tri-State Mining District in areas of Cherokee County, KS and Jasper and Newton counties, MO. It is joined by several tributaries in Oklahoma including Beaver Creek and Quapaw Creek, both of which drain the TCSS. Where the two rivers join, the Grand River begins. Before the Grand River becomes Grand Lake, it receives mine drainage from Newton County, MO via Lost Creek. Tribal gathering practices frequently occur in riparian habitats since they support a diverse and rich ecosystem of plants and animals that are important for subsistence. As seen in Figure 2, plant tissue sampling sites were chosen in areas previously shown to have heavy metal contamination within floodplain soils of Tribal jurisdictions (Garvin et al., 2010). The latitude and longitude of these sampling locations are shown in Table 1.

Field and Laboratory Procedures

All field and laboratory procedures followed those approved within the sampling analysis plan (SAP)³. The specific plant organ that is used by Tribes was sampled for each species. Roots or rhizomes were dug with a stainless steel trowel and removed from the plant using stainless steel scissors. Leaves, stems, or fruit were also collected from plants using stainless steel scissors. All samples were rinsed thoroughly with deionized water, placed in a resealable plastic bag, and stored at 4 °C until shipment. Sampling equipment was sterilized between each use by scrubbing with Liquinox® and rinsing with deionized water. Concentrations of Cd, Pb, and Zn in plant samples were analyzed by ACZ Laboratories in Steamboat Springs, Colorado. Concentrations were determined using inductively coupled plasma-mass spectrometry (ICP-MS) using EPA Method 6020.

Soil samples analyzed within this study were based on previous collected data from Garvin et al. 2010, and sample collections consisted of the following procedures. Using a stainless steel trowel and bowl, a composite soil sample (15 cm deep) was collected from designated floodplain sites. Samples were refrigerated at 4 °C until shipment. Sampling equipment was sterilized between each use by scrubbing with Liquinox® and rinsing with deionized water. Samples were transferred to white Dixie® bowls, oven dried at 110 °C for 8 hours, and then ground with a mortar and pestle to break the sample apart, but making sure not to pulverize any portion of the sample. The sample was then passed through a 5-, 10-, 35-, 60-, 120-, and 230-mesh sieve to achieve a homogenized sample that was less than 63 μ m (clay

³ The SAP was approved by the Tar Creek Trustee Council and is available online at <<u>http://www.ottawatribe.org/wp-content/uploads/2001/04/CRISAPfinal133.pdf</u>>.

fraction). A portion of the sieved sample was placed in a 31.0 mm polyethylene sample cup so that one-half to two-thirds of the sample cup was full. The sample cup was then covered with a 2.5 μ m Mylar film for analysis. The remaining homogenized portions of all samples were stored in ZiplocTM bags. All equipment including mortar, pestle, and sieves were thoroughly sterilized between each use by scrubbing with Liquinox[®] and rinsing with deionized water. X-ray Fluorescence (XRF) screening was performed at the Cherokee Nation Environmental Office in Tahlequah, Oklahoma by a certified operator (Garvin et al., 2010).

Calculation of Provisional Tolerable Weekly Intakes

Acceptable or tolerable intakes of Cd, Pb, and Zn have been established by the Joint Food and Agriculture Organization (FAO)/World Health Organization (WHO) Expert Committee on Food Additives (FAO/WHO, 2004). These limits are referred to as the provisional tolerable weekly intake (PTWI) and represent the acceptable human weekly exposure to contaminants within foods. The PTWI is based on the number of mg of contaminant that is consumed per kg of body weight per week. As seen in Table 2, the established PTWI limit of Cd is 0.007 mg/kg/week, Pb is 0.025 mg/kg/week, and Zn is 7 mg/kg/week (FAO/WHO, 2004). This can be further understood that for every kg a person weighs, they may consume 0.007 mg Cd, 0.025 mg Pb, and 7 mg Zn per week. Using the established PTWI limits, the PTWI of any individual can be calculated based on their weight. Thus, a child weighing 23 kg may consume 0.161 mg Cd, 0.575 mg Pb, and 161 mg Zn per week. Similarly, an adult weighing 70 kg may consume 0.49 mg Cd, 1.75 mg Pb, and 490 mg Zn per week.

10 2	2. Trovisional tolerable weekly make (1 1 w1) mints for ed, 1 b, and 2n for emidten (25 kg) and addres (70 kg).						
-	Additivo	Established PTWI limit	PTWI of a	PTWI of a			
_	Additive	per kg body weight ^a	23 kg child	70kg adult			
	Cd	0.007	0.161	0.49			
	Pb	0.025	0.575	1.75			
	Zn	7	161	490

^a provisional tolerable weekly intake limit (mg/kg body weight/week) established by the Joint FAO/WHO Expert Committee on Food Additives.

Serving size and frequency of consumption are variables that influence metal exposure. Typical serving sizes of each culturally significant plant species that were sampled within this study are shown in Table 3. These data were used to calculate the percentage of the PTWI that was obtained for heavy metals by consuming one serving of a specific plant species for an average child (23kg) and an average adult (70kg).

^a f = fruit, l = leaves, r = root, s = stem, w = whole plant. ^b serving size is approximated on what a child Tribal member weighing 23 kg typically consumes.

^c serving size is approximated on what an adult Tribal member weighing 70 kg typically consumes.

Statistical Analysis

All statistical tests were performed using Statistica 9 software (Statsoft®, Tulsa, OK). Normality was tested using two methods; firstly, by using histograms to visually inspect the data and secondly, by performing two statistical tests for normality (Kolmogorov-Smirnov and Shipiro-Wilks). All parameters tested were non-normal. Therefore, it was concluded that non-parametric statistical analyses would be used in all cases. Statistical differences between two groups of data were determined using the Mann-Whitney U test for independent samples. Statistical comparisons between groups of data were made using the Spearman Rank Order correlation test. All statistical analyses were performed at a 95% confidence interval.

RESULTS AND DISCUSSIONS

Heavy Metal Concentrations in Culturally Significant Plants

Background levels for each plant species sampled were determined by observing the lowest recorded value for Cd, Pb, and Zn in control samples. In almost all instances, background levels for Cd, Pb, and Zn were exceeded for plant samples (on a species by species basis) taken within impacted areas. Additionally, no single sample measured below the background concentration for all three trace metals. These data are presented in Appendix B.

Culturally significant plant tissues were collected from individuals within the floodplain that were located near the same transects sampled in a sediment/soil XRF study by Garvin et al. (2010). Soil data from Garvin et al. (2010) are shown in Appendix C. As seen in Table 4, plant tissue metal concentrations for Pb and Zn were compared to concentrations within the soil. Lead concentrations in plant tissues and soil were significantly, positively correlated (r = 0.48, p = 0.00). Zinc concentrations in plant tissues and soil were also significantly, positively correlated (r = 0.70, p = 0.00). These results indicate a contamination pathway in which culturally significant plants are exposed to heavy metal concentrations via floodplain soils.

Correlation	r	p - value	n
Lead Plant vs. Soil	0.48	0.00	285
Zinc Plant vs. Soil	0.70	0.00	291

Table 4: Results of a correlation analysis for Pb and Zn concentrations in plant tissues and clay fraction of floodplain soils (soil data from Garvin et al., 2010).

Using plant tissue heavy metal concentration data and serving size estimations for Tribal consumption, the PTWI was calculated for Cd, Pb, and Zn of each culturally important species at each sampling location. These data are shown in Appendix B, and indicate the percentage of the PTWI that is consumed (for each trace metal) should a child (weighing 23 kg) and adult

(weighing 70 kg) consume only one serving of a particular plant species. In Table 5, the number and percentage of plant tissue samples (n = 202) with concentrations of Cd, Pb, and Zn⁴ that exceeded the PTWI are shown. For a child, 35% of plant tissue samples exceeded metal concentration the PTWI (with only one serving) for Cd, 42% for Pb, and 2% for Zn. For an adult, 21% exceeded the PTWI for Cd, 34% for Pb, and 1% for Zn. These results indicate that Tribal consumption of only one serving of culturally important species per week from impacted gathering areas pose serious health risks from exposure of Cd and Zn to Tribal members, especially to children.

Table 5: Number and percentage of plant tissue samples (n = 202) that exceeded the PTWI for Cd, Pb, and Zn with only one serving.

Number/Percentage	Child (23 kg)			Adult (70 kg)		
Trumber/Tereentuge	Cd	Pb	Zn	Cd	Pb	Zn
# Samples in Exceedance of PTWI	70	85	3	45	69	2
% Samples in Exceedance of PTWI	35%	42%	2%	21%	34%	1%

DETERMINATION OF INJURY AND CONCLUSIONS

Culturally important plant species growing within the floodplain habitats of the Grand Lake watershed that are exposed to heavy metal releases from the TSMD contain highly elevated concentrations of Cd, Pb, and Zn compared to background concentrations. Since a significant, positive correlation was shown for metal concentrations in plant tissues and soil (Pb: r = 0.48, p = 0.00; Zn: r = 0.70, p = 0.00), these results identify a pathway to culturally significant plants from heavy metal in floodplain soils. Results have shown an abundance of culturally significant plants still available for Tribal use even though there are very high concentrations of heavy metals in the soils. The metal exposure to Tribal members who gather at these locations is of serious concern because of the established contamination pathway to plants via soil.

As defined by the DOI, an injury to a biological resource has resulted from a release of a hazardous substance if the concentration of the substance is sufficient to exceed action or tolerance levels established under section 402 of the Food, Drug and Cosmetic Act, 21 U.S.C. § 342, in edible portions of organisms. 43 CFR § 11.62(f)(1)(ii). The regulations further specify that [i]njury to biological resources, as such injury is defined in § 11.62(f)(1)(ii), may be determined by using methods acceptable to or used by the Food and Drug Administration or the appropriate State health agency in determining the levels defined in that paragraph. 43 CFR § 11.64(f)(3). Methods that FDA accepts or uses for these purposes include those used by the Joint Food and Agriculture Organization (FAO)/World Health Organization (WHO) Expert Committee on Food Additives to establish tolerable human intakes of Cd, Pb, and Zn contained

⁴ Even though there are few exceedances of the PTWI with respect to Zn, it is important to include since Zn is colocated with Cd and Pb.

in foods (B. Harper, personal communication, March 11, 2014). These limits are referred to as the provisional tolerable weekly intake (PTWI) and represent the acceptable human weekly exposure to contaminants within foods (FAO/WHO, 2004).

Injury to plant species that are culturally important to the Six Treaty Tribes of Oklahoma can therefore be determined based on their exceedance of the PTWI levels for Cd, Pb, and Zn. The calculations of the PTWI within this study were based on a Tribal member, adult or child, eating only one serving per week of a culturally important plant species. Results showed that: 35%, 40%, and 2% of samples exceeded the PTWI for a child (23 kg) for Cd, Pb, and Zn, and 21%, 33%, and 1% of samples exceeded the PTWI for an adult (70 kg), respectively (Table 5). Injured species were found to be widespread across the study area and were collected adjacent to all the water bodies in question in this study; namely, Tar Creek, Elm Creek, Lost Creek, Spring River, and Grand River. Of the 36 species sampled, 33 were found to be injured (92%) for at least one sampling location for at least one metal. Injured species include: arrowhead root, black willow, bracken fern, buckbrush, buttercup, common milkweed, common mullein, common plantain, creeping wood-sorrel, curly dock, dandelion, duckweed, green dragon, greenbrier, Jackin-the-pulpit, jewelweed, pawpaw, peppergrass, poke, river birch, solomon's seal, violet, white mulberry, wild blackberry, wild carrot, wild ginger, wild grape, wild lettuce, wild mint, wild potato-vine, and wild strawberry. The number and relative percentage of injured species found at each sampling site are shown in Table 6. The full list of injured species at each sampling site can be seen in Appendix D.

		Site

Table 6: Number and percentage of injured plant species based on PTWI exceedances of Cd, Pb, and Zn (by consuming only one serving per week) found at each sampling site.

The degree of exceedance of the PTWI for each metal was another important aspect to consider. For example, a duckweed sample from TC1 had 7,547%, 6,743%, and 1,118% exceedance of the PTWI values for Cd, Pb, and Zn, respectively. Table 7 shows the numbers of samples that exceeded the PTWI for Pb, Zn, and Cd to different degrees.

	Number of Exceedances					
Degree of		Child $(n - 202)$			Adult $(n - 202)$	
Exceedance	DL	(II = 202)	CI	DL	(II = 202)	C I

Table 7: Number and degree of exceedance of the PTWI (by consuming only one serving per week) for Cd, Pb, and Zn of plant tissue samples (n = 202) for a typical child or adult.

It is important to clarify that the majority of Tribal members are likely eating much more than one serving of one species per week (i.e. multiple servings of multiple species are eaten daily). If a Tribal member were to consume one serving of a particular plant that contained greater than 100% of the PTWI (per their body weight) for a metal then they could not safely consume any more of that metal within a seven day period. As such, service loss due to [i]njuries to plant species are most likely greater than what is estimated within this study, and Tribal health is more at risk.

In order to better understand the severity of exposure to heavy metals within the diets of Tribal members, a weekly consumption scenario has been included in this discussion. As seen in Table 8, the consumption scenario consists of a hypothetical weekly diet of a Tribal member living within the Grand Lake watershed. It is assumed that the Tribal member actively consumes traditional plants from gathering areas that were sampled within this study. All traditional food items chosen within the scenario have been shown to be commonly eaten by Tribal members (Garvin et al., 2011). Within the scenario, each food item is based on one serving size (see Table 3). The PTWI is calculated only for traditional plants that were hypothetically gathered from locations within this study (It is important to mention that fish are commonly harvested within the Grand Lake watershed, and therefore present an major exposure pathway via consumption as well (ODEQ 2003, 2007)). If an adult Tribal member were to follow the weekly consumption scenario as part of their diet, they would have consumed 17,054% of their allowable weekly limit intake for Cd, 22,461% for Pb, and 2,320% for Zn (see Table 9). Additionally, a child Tribal member would have consumed 25,952% of their allowable weekly limit for Cd, 34,180% for Pb, and 3,531% for Zn (see Table 10). These calculations highlight the severe magnitude of heavy metal exposure to Tribal members who gather and consume traditional plants within the Grand

Lake watershed. As a product of this research, Tribes and government entities will be better equipped to make decisions on managing natural resources that will be protective of Tribal health and traditional lifeways.

Day	Breakfast	Lunch	Dinner
Monday	eggs wild onions (TC-1) toast blackberry jam (SR-3)	chicken sandwich chips	fish wild ginger (SR-2) common milkweed (SR-7) poke (SR-3) bread
Tuesday	cereal milk toast blackberry jam (SR-3) spicebush tea (SR-2)	fish poke (SR-3) dandelion (SR-3) peppergrass (SR-3) wild onions (TC-1)	venison hominy wild potato (TC-2) poke (SR-3) bread
Wednesday	eggs wild onions (TC-1) toast strawberry jam (LC-1)	fish poke (SR-3) dandelion (SR-3) peppergrass (SR-3) wild onions (TC-1)	venison corn duckweed soup (TC-1) wild onions (TC-1) bread
Thursday	eggs wild onions (TC-1) venison toast elderberry jam (SR-1)	ham sandwich chips	chicken mashed potatoes common milkweed (SR-7) poke (SR-3) bread
Friday	cereal milk toast blackberry jam (SR-3) wild mint tea (LC-1)	poke (SR-3) dandelion (SR-3) bracken fern (SR-1) wild lettuce (EC-1) wild onions (TC-1)	fish hominy poke (SR-3) dandelion (SR-3) peppergrass (SR-3) wild onions (TC-1) bread
Saturday	eggs wild onions (TC-1) venison toast blackberry jam (SR-3)	chicken sandwich chips	fish wild ginger (SR-2) common milkweed (SR-7) poke (SR-3) bread
Sunday	eggs wild onions (TC-1) venison toast blackberry jam (SR-3)	venison corn duckweed soup (TC-1) wild onions (TC-1) bread	fish hominy poke (SR-3) dandelion (SR-3) peppergrass (SR-3) wild onions (TC-1) bread

Table 8: Tribal consumption scenario: a hypothetical weekly diet of a Tribal member who consumes traditional plants growing in gathering locations sampled within this study.

*Elm Creek (EC), Lost Creek (LC), Spring River (SR), and Tar Creek (TC). Reflects the location at which the plant species was gathered from.

*Assume each food item within each meal is based on one serving size (see Table 3).

*Assume fish and venison are collected by Tribal members within the Grand Lake watershed.
